PUBLICATIONS	<p>“The Equity Risk Premium: A Review of Models” (with Carlo Rosa) <i>Federal Reserve Bank of New York Economic Policy Review, Volume 21, Number 2, December 2015</i></p> <p><i>Abstract:</i> We estimate the equity risk premium (ERP) by combining information from twenty models. The ERP in 2012 and 2013 reached heightened levels —of around 12 percent— not seen since the 1970s. We conclude that the high ERP was caused by unusually low Treasury yields.</p> <p>“Monetary Policy and Financial Conditions: A Cross-Country Study” (with Tobias Adrian, Federico Grinberg and Tommaso Mancini-Griffoli) <i>Chapter 7, Advancing the Frontiers of Monetary Policy, Tobias Adrian, Doug Laxton and Maurice Obstfeld, editors, International Monetary Fund, Washington DC, April 2018</i></p> <p><i>Abstract:</i> Loose financial conditions forecast high output growth and low output volatility up to six quarters into the future, generating time varying downside risk to the output gap which we measure by GDP-at-Risk (GaR). This finding is robust across countries, conditioning variables, and time periods. We study the implications for monetary policy in a reduced form New Keynesian model with financial intermediaries that are subject to a Value at Risk (VaR) constraint. Optimal monetary policy depends on the magnitude downside risk to GDP, as it impacts the consumption-savings decision via the Euler constraint, and the financial conditions via the tightness of the VaR constraint. The optimal monetary policy rule exhibits a pronounced response to shifts in financial conditions for most countries in our sample. Welfare gains from taking financial conditions into account are shown to be sizable.</p>	
WORKING PAPERS	<p>“Fire-Sale Spillovers and Systemic Risk” (with Thomas Eisenbach) <i>Revise and resubmit, Journal of Finance, February 2019</i></p> <p><i>Abstract:</i> We reveal and track over time the factors that make the financial system vulnerable to fire sales by constructing an index of aggregate vulnerability. The index starts increasing in 2004, before any other major systemic risk measure, more than doubling by 2008. The fire-sale specific factors of delevering speed and concentration of illiquid assets account for the majority of this increase. Individual banks’ contributions to aggregate vulnerability are an excellent five-year-ahead predictor of SRISK. Had they been available at the time, these balance sheet-based measures would have been a useful early indicator of when and where vulnerabilities were building up.</p> <p>“Time-Varying Inflation Risk and Stock Returns” (with Martijn Boons, Frans de Roon, and Marta Szymanowska) <i>Revise and resubmit, Journal of Financial Economics, January 2019</i></p> <p><i>Abstract:</i> We show that inflation risk is priced in stock returns and that inflation risk premia in</p>	

the cross-section and the aggregate market vary over time, even changing sign as in the early 2000s. This time variation is due to both price and quantities of inflation risk changing over time. Using a consumption-based asset pricing model, we argue that inflation risk is priced because inflation predicts real consumption growth. The historical changes in this predictability and in stocks' inflation betas can account for the size, variability, predictability and sign reversals in inflation risk premia.

“Financial Vulnerability and Monetary Policy” (with Tobias Adrian)

Abstract: We present a microfounded New Keynesian model that features financial vulnerabilities. Financial intermediaries' occasionally binding value at risk constraints give rise to variation in the pricing of risk that generate time varying risk in the conditional mean and volatility of the output gap. The conditional mean and volatility are negatively related: during times of easy financial conditions, growth tends to be high, and risk tends to be low. Monetary policy affects output directly via the IS curve, and indirectly via the pricing of risk that relates to the tightness of the value at risk constraint. The optimal monetary policy rule always depends on financial vulnerabilities in addition to the output gap, inflation, and the natural rate. We show that a classic Taylor rule exacerbates deviations of the output gap from its target value of zero relative to an optimal interest rate rule that includes vulnerability. Simulations show that optimal policy significantly increases welfare relative to a classic Taylor rule. Alternative policy paths using historical examples illustrate the usefulness of the proposed policy rule.

“How to Escape a Liquidity Trap with Interest Rate Rules”

Abstract: I study how central banks should communicate monetary policy in liquidity trap scenarios in which the zero lower bound on nominal interest rates is binding. Using a standard New Keynesian model, I argue that the key to preventing self-fulfilling deflationary spirals and anchoring expectations is to promise to keep nominal interest rates pegged at zero for a length of time that depends on the state of the economy. I derive necessary and sufficient conditions for this type of state contingent forward guidance to implement the welfare maximizing equilibrium as a globally determinate (i.e., unique) equilibrium. Even though the zero lower bound prevents the Taylor principle from holding, determinacy can be obtained if the central bank sufficiently extends the duration of the zero interest rate peg in response to deflationary or contractionary changes in expectations or outcomes. Fiscal policy is passive, so it plays no role for determinacy. The interest rate rules I consider are easy to communicate, require little institutional change and do not entail any unnecessary social welfare losses.

“Empirical Network Contagion for US Financial Institutions” (with Collin Jones)

Abstract: We construct an empirical measure of expected network spillovers that arise through default cascades for the US financial system for the period 2002-2016. Compared to existing studies, we include a much larger cross-section of US financial firms that comprise more than 80% of total domestic financial assets, capturing all bank holding companies, all broker-dealers, all insurance companies, and all real estate investment trusts. We find negligible expected spillovers from 2002 to 2007 and from 2013 to 2016. However, between 2008 and 2012, we find that default spillovers can amplify expected losses by up to 20%, a significantly higher estimate than previously found in the literature.

“Cross-sectional inflation risk in menu cost models with heterogeneous firms”

Abstract: We show that firms in models with menu costs, when calibrated to have the empirically observed frequency and size of individual-goods price adjustments, have stock returns that are always positively correlated with inflation. The cross-sectional dispersion in this correlation is almost negligible, even though firms have very diverse micro-level pricing behavior. Because in this class of models positive nominal shocks are good states of nature and the correlation between stock returns and inflation is positive, agents are willing to pay a premium to hold assets whose returns covary negatively with inflation. In contrast, we empirically find that the dispersion in the correlation between stock returns and inflation is about 100 times larger than in the model, and that correlations are negative about half the time. Furthermore, and also at odds with sticky-price models, investors require a premium to hedge against states of high inflation. Because firms' heterogeneity is the key

mechanism that generates a high degree of monetary non-neutrality in the models, our results suggest that we do not yet have a full account of the monetary transmission mechanism, and that asset prices can provide important information about it.

“Investment and Stock Market Volatility” (with Leonid Kogan and Dmitry Livdan)

Abstract: We study the relation between returns on the aggregate stock market and aggregate real investment. While it is well known that, controlling for productivity, the aggregate investment rate is negatively related to subsequent excess stock market returns, we find that it is positively related to future stock market volatility. Thus, conditionally on past aggregate investment, the mean-variance tradeoff in aggregate stock returns is negative. We interpret this puzzling pattern within a general equilibrium production economy. In our model, investment is determined endogenously in response to two types of shocks: shocks to productivity, and shocks to aggregate risk aversion that affect the cost of capital. Investment is positively related to productivity and negatively related to the cost of capital. Controlling for productivity, high-investment periods tend to correspond to low cost of capital, giving rise to a negative relation between aggregate investment and expected excess stock market returns. When cost of capital is low, and thus close to the growth rates of cash flows, stock prices are relatively sensitive to changes in discount rates and stock returns become relatively volatile, giving rise to a positive relation between investment and future stock market volatility. Consequently, our results indicate that the time-varying price of aggregate risk is an important determinant of aggregate investment dynamics.
